**Dedication**

*To my family, for their sacrifice*

## **ACKNOWLEDGMENTS**

All praise belongs to Allah, lord of all that exists and then to my advisor, Dr. Abdulaziz Al-Saadi, my committee members; Dr. Nisar Ullah, Dr. Tawfik Saleh, Dr. M.R.S.A. Janjua and Dr. Sulayman Oladepo. I appreciate the support of the faculty and staff of Chemistry department especially Dr. Abulkibash, Dr. Chanbasha and Dr. Al-Hooshani. Also, I would like to appreciate Dr. Abdullah Sultan, Dr. Safwat Abdelazeim and Dr. Alexis Nzila. I am most grateful to the members of the Nigerian community in KFUPM for their help in several ways particularly; Mr. Kazeem Sulaiman, Dr. Saheed Popoola, Dr. Saheed Adekunle, Mr. Nasirudeen Ogunlakin, Mr. Cheche Abubakar; who doubled as my room and class mate, Mr. Isaiah Adelabu, Mr. Ismail Yunus, and Mr. Kabiru Haruna. I would also like to appreciate my friends from other nationalities particularly Dr. Adam Seliman, Mr. Faisal Alrasheed and Mr. Mutasem Al-Shalalfeh. My appreciation would be incomplete without appreciating the sacrifice of my family, most especially my wife, Rukayat and my son, Abdus-Samad; and to my siblings and parents for taking care of them during my absence. I pray and hope the sacrifice would be worth it.

## ABSTRACT

Full Name : Abdulmujeeb Toluwase Onawole  
Thesis Title : Quantum chemical and spectroscopic studies of clotrimazole and resorcinol  
Major Field : Chemistry  
Date of Degree : May, 2017

Bioactive compounds such as clotrimazole and resorcinol are important antimicrobial agents. Clotrimazole is effective against Candidiasis while Resorcinol is used in treating acne. Quantum chemical studies such as Density Functional Theory (DFT) and molecular docking are important tools in understanding the molecular properties of bioactive compounds most especially the mode of action by which they act as drugs. Understanding these properties would help in future drug development especially now that most microbes are developing resistance to already approved drugs. Computational analysis and spectroscopic characterizations of clotrimazole, resorcinol, resorcinol -OD isotopomer, and resorcinol dianion salt were investigated. Infrared and Raman spectroscopic techniques were used for the structural characterization. Conformational analysis using potential energy surface scans via DFT was done for both clotrimazole and resorcinol. The energetically minimized forms and vibrational spectra were computed using ab initio and DFT quantum chemical techniques utilizing 6-311++G(d,p) basis sets. The unit cell of the room-temperature stable  $\alpha$ -resorcinol and its -OD isotopomer were optimized at the B3LYP/6-311+G (d,p) level of theory and was shown to adopt a near Cs symmetry. Assignments of local vibrational modes associated with the crystal structure were also carried out. Relative stability analysis from the MP4 level, the syn-syn (S) form of resorcinol is predicted to be about 0.8 kcal/mol higher in energy than the most stable anti-syn (AS) form. The out-of-plane vibrational modes of the solid sample exhibit some spectral shifts as compared to the gaseous phase as a result of the strong intermolecular packing forces. Molecular docking study exhibited that resorcinol is keratolytic active and

tends to form a stable complex in its near-AS form with Keratin-7. The conformational analysis of clotrimazole gave rise to three possible conformers. The geometrical parameters calculated at (B3LYP/6-311++G(d,p)) of the clotrimazole were in agreement with the XRD results. The calculated FMO energies gave insight into the molecular properties which disclosed that charge transfer occurs in the molecule and showed that the HOMO occurred on the imidazole ring while the LUMO occurred on the benzene rings. The MEP map showed that the negative region is localized in the imidazole ring and hence prone to electrophilic attack. The protein-ligand interaction of the title compound with Secreted Aspartic Proteinase 2 of *C. albicans* using molecular docking studies gave insight into its mode of action in treating Candidiasis.

## ملخص الرسالة

الاسم الكامل: عبدالمجيب تلويش أونانول  
عنوان الرسالة: دراسة التحليل الطيفي وكيمياء الكم لمركبات كلوترايمازول والريسورسينول  
التخصص: علوم الكيمياء  
تاريخ الدرجة العلمية: مايو 2017

الكلوترايمازول والريسورسينول هما من المركبات ذات الفاعلية الحيوية التي تلعب دوراً مهماً كعوامل متضادة للميكروبات. الكلوترايمازول فعال ضد فطريات الجلد بينما الريسورسينول تكمن فعاليته في معالجة حب الشباب. وتعتبر دراسات كيمياء الكم مثل نظرية الكثافة الوظيفية ونظرية الإلتحام الجزيئية كأدوات مهمة لمعرفة الخصائص الجزيئية لهذه المركبات ذات الفاعلية الحيوية وبالأحرى معرفة طريقة عملها كأدوية. معرفة خصائص هذه المركبات قد تمكن في المستقبل من تطوير الادوية خصوصاً مع تطوير الميكروبات لمقاومتها ضد الأدوية المسموح بها حالياً. تم تشخيص مركبات الكلوترايمازول والريسورسينول والريسورسينول المتناظر بالإضافة إلى الريسورسينول ثنائي الملح بواسطة التحليل المحوسب والتوصيف الطيفي. وكذلك استخدمت تقنية مطيافية الأشعة تحت الحمراء ومطيافية رامان في التوصيف التركيبي لهذه المركبات. تحليل التكوين الجزيئي للكلوترايمازول والريسورسينول أجرى بماسح طاقة السطح الموضوعية باستخدام نظرية الكثافة الوظيفية. الأطياف الاهتزازية والانماط المختزلة بالطاقة حوسبت بواسطة تقنيات نظرية الكثافة الوظيفية وابانيشو باستخدام

6-311++G(d,p) basis sets.

وحدة الخلية المثلي لاستقرار الريسورسينول والريسورسينول المتماثل في درجة حرارة الغرفة تم ضبطها بواسطة B3LYP/6-311+G (d,p) level of theory والتي تتخذ عرض ذرات الكربون المتماثلة القريبة

كما تم تحديد أنماط الاهتزازات المحلية المرتبطة بالشكل البلوري. تحليل الاستقرار النسبية من مستوى

MP4 and the syn-syn (S) form و

للريسورسينول قدر بحوالي 0.8 كيلو سعر لكل مول له طاقة أكثر من

the most stable anti-syn (AS) form.

أنماط الاهتزازات خارج السطح للعينة الصلبة أوضحت تغيرات طيفية مقارنة بالحالة الصلبة نتيجة لقوة الجزيئات البينية لقوي التعبئة. دراسة إلتحام الجزيئات أوضحت ان الريسورسينول نشط للقرنية وله ميل لتكوين مركب مستقر فى متشاكله اي اس مع الكيراتين-7.

تحليل التكوين الجزيئ للكلوترايمازول اعطي ثلاثة متشاكلات محتملة. تم حساب عوامل الشكل الهندسى على قاعدة

(B3LYP/6-311++G(d,p))

للكلوترايمازول والتي لها توافق مع نتائج حيود الاشعة السينية. طاقات اوربتالات جزيئات فيرمى المحسوبة بالنسبة للخصائص الجزيئية أوضحت حدوث إنتقال الشحنة فى الجزيئ وبناءً عليها فإن الاوربتالات الجزيئية الممتلئة العليا تحدث علي حلقة الاميدازول بينما الاوربتالات الجزيئية الفارغة الدنيا تحدث علي حلقات البنزين. أوضحت خريطة ام اي بي إن المنطقة السالبة تقع على حلقة الاميدازول نتيجة للهجوم الالكتروفيلى. تفاعل البروتين- اللاقطة بالنسبة للمركبات موضوع الدراسة مع أسبارتك بروتينيز-2 المستخلص من سى ألبىكان بإستخدام دراسات إلتحام الجزيئات اعطى نظرة فاحصة لطريقة عمل هذه المركبات لعلاج فطريات الجلد.

# CHAPTER 1

## INTRODUCTION

Antimicrobial agents which are compounds that destroys microorganisms including fungi, bacteria and other microbes are often classified based on the microorganism they act upon. Clotrimazole acts on the fungus *Candida albicans* which is the pathogen for candidiasis[1] and hence it is called an antifungal while Resorcinol is active against *Propionibacterium acnes* the bacterium that causes hidradenitis suppurativa (acne)[2], [3] hence, it is an antibacterial drug. Quantum chemical studies which includes Density Functional Theory (DFT) and Molecular docking have been widely used in studying bioactive compounds and classified under *in silico* methods [4] in drug discovery which is literally means in silicon referring to the silicon chips in computers.

Designing drugs used to be a very expensive and cumbersome process. However, the advent of Computational Chemistry has proved a very useful tool in Medicinal Chemistry and in understanding the mechanisms by which drugs function. This information is important because it helps in the designing of new drugs [5]. Also Computer-Aided Drug Designing (CADD) has helped in reducing the cost in both time and money of drug development [6] Stereochemical behavior often influences the physicochemical properties of a compound [7]. For bioactive compounds, they have a particular influence on a molecule's ability to interact with a protein target. Molecular docking involves predicting the most preferred conformation or orientation of a small molecule (bioactive compound)

when it bounds to a large molecule (protein). The way the small molecular binds to the protein can help predict the binding affinity and also the mode of action of that small molecule. Spectroscopy is also an important tool in drug design especially when it comes to characterization during drug delivery and drug formulation [8]. This is very important in how a drug is absorbed in the body. DFT complement the experimental spectra in assigning vibrational bands so as to distinguish the different functional groups present in bioactive compounds. Upon the application of molecular docking in understanding the mode of action of resorcinol and clotrimazole which are approved drugs. Molecular docking was applied in methimazole and ketoconazole and also newly synthesized piperazine and inorganic complex compounds which showed promise as anti-stress and anticancer agents respectively.

## 1.1 Clotrimazole

Clotrimazole (CTZ), 1-[(2-Chlorophenyl)(diphenyl)methyl]-1H-imidazole is a derivative of imidazole and is being used to treat fungal or yeast infections that affects the skin areas such as the feet (Athlete's foot) and even the vagina. It is mainly used to treat candidiasis, a fungal disease, which is caused by the pathogen *Candida albicans* (*C. albicans*). CTZ is applied as a cream on the affected areas of the skin or it is taken orally in tablet form. It is presumed that it inhibits the proteins in the fungal cell membrane which leads to the permeability of the membrane and ostensible disturbance of the enzymes bound to the membrane [9], [10]. *C. albicans* is an important agent of infection, which engages in a parasitic relationship with its host especially when the hosts have deficient immune system such as HIV/AIDS (Human Immuno-deficiency Virus/Acquired Immuno-deficiency Syndrome). Several studies have been directed on understanding the cell surface of *C.*

*albicans* mainly because of the two main functions of the cell surface which includes maintenance of the shape of the fungus acting as a permeable membrane and secondly, the interaction of the fungi with its external environment which include its host [11]. The latter part of the function of the cell surface highlights the reason why most research is on the cell surface of *C. albicans*. *Candida albicans* is the most common strain of *Candida* which is the pathogen for Candidiasis [12]. Over 150 species of *Candida* exist some of which include *C. tropicalis*, *C. krusei* and *C. glabrata*. *Candida* can be found in all humans. Their cell walls are thin and they are about 6 microns in length. They actually exhibit a commensal relationship in humans [13]. However, when their reproduction is in excess they become parasitic. The presence of virulent secreted aspartic proteases (SAPs) and other metabolites lead to a disruption in the energy cycle and hence fatigue in the host. Curd-like discharge from the vagina and white patches in the tongue area are a few symptoms of Candidiasis [14]. Anti-fungal agents such as CTZ and other Imidazole related compounds like fluconazole and ketoconazole are used in treating Candidiasis [15]. CTZ has been known to display its antimycotic activity by inhibiting the fungi cytochrome p450 14 $\alpha$ -lanosterol-demethylase (14-LD) commonly referred to as CYP51 [16]. This is done by restraining the biosynthesis of the sterol in particular the sterol auxotrophic strain including the demethylase [17]. This makes the membrane permeable and leads to a disruption between the enzymes and the membrane it bounds on. This action of CTZ prevents the further division and growth of *C. albicans*. However, there are speculations that CTZ may also interact with phospholipids and other proteins in the cell membrane of *C. albicans* [10]. Bilensoy et al [18] and Robbe et al [19] reported the experimentally observed IR and Raman spectra of CTZ respectively while Dhudashi et al [20] used HPLC

method to estimate the CTZ in lotion and cream dosage form. Song and Shin [1] reported the XRD crystal structure of the title compound. In this present work, the conformational analysis, molecular and spectroscopic properties including vibrational assignments have been reported which to the best of our knowledge has not been done till date. Molecular docking studies of CTZ with a virulent protein present in *C. albicans* using the possible conformations was also reported to give insight into the possible mode of action of CTZ in the cell membrane of *C. albicans*

## 1.2 Resorcinol

Resorcinol (1,3-dihydroxybenzene) is a fundamental organic compound that finds several applications in pure and applied fields of science [6,7]. Because of its pharmacological and biological importance, especially as a potent antibacterial agent [1], resorcinol remained a subject of extensive studies for its electronic ground and excited states from experimental and theoretical points of view. Resorcinol is a simple chemical compound that has been in use for more than a century. Nevertheless, it is not widely known despite its many applications except among non-specialist in the field of resorcinol chemistry [21], [22]. Resorcinol is a white crystalline solid which often exist in both  $\alpha$  and  $\beta$  form which are both formed by the crystallization of resorcinol from ethanol and benzene respectively [21]. Resorcinol is a relatively less toxic compound compared to phenol [23]. Hence, its use in the pharmaceutical industry. It can easily be absorbed by the skin and causes irritation upon exposure to the eyes and during inhalation. However, it is stable under flammable conditions [24]. 2-methoxy resorcinol is a derivative of pyrogallol, a toxic natural product [25] mostly found in plants. However, its applications are found in supramolecular

photochemistry [26] and also has a uremic retention solute used in recognizing protein-bound compounds [27].

Halogenated resorcinols are one of the most useful derivatives in resorcinol chemistry. They are formed via electrophilic aromatic substitution with the respective halogen atom. The presence of two hydroxyl groups cause higher activation, which consequently allows easy halogenation of resorcinol at the 2, 4 and 6 positions. Fluoro resorcinols are used in dye preparation, particularly fluorescein and rhodol dyes, 2-chloro resorcinol is a precursor in preparing 1,2-benzisoxazoloxy acetic acids, which is an antihypertensive drug while 4-chloro resorcinol is used in preparing photoactive compounds which are applied in photolithography. Brominated and iodinated resorcinol compounds are used to alleviate the impact caused by fires and in radiology diagnosis respectively [22].

During the past decades resorcinol exhibited a number of medical applications, especially as it is used as a starting material to produce derivatives of Active Pharmaceutical Ingredients (API) for treating Alzheimer's disease, sickle cell anemia and alcoholism [22]. However, resorcinol itself has been also used as a topical agent in treating dermatological diseases such as eczema, acne and Hidradenitis Suppurativa (HS) [29,30]. Molecular docking is a useful tool used in structure-based drug design (SBDD) to predict binding affinities of an API with specific protein targets [30] that play a role in the pathology of a disease. Resorcinol possess keratolytic properties and hence is known to target the follicular keratin plug which is the initiation stage of several HS lesions [29]. Therefore, a molecular docking analysis is useful to provide insights on the modes of action of resorcinol in treating HS.

## CHAPTER 2

### LITERATURE REVIEW

#### 2.1 Clotrimazole

*Candida albicans* is one of the popular fungal pathogens responsible for causing Candidiasis. It engages in a parasitic relationship with its host even though it initially engages in a commensal relationship [11], [31]–[33]. This parasitic relationship is often worse when it occurs in that hosts have deficient immune systems, such as HIV/AIDS because they have T-cell deficiencies [11]. Though it is still unclear in mycology how the relationship changes from commensal to parasitic [31]. Candidiasis also particularly affects about 75% of the women population experience candidiasis in the form vulvovaginal candidiasis [34]. *C. albicans* are also known to play a role in early childhood caries which is the presence of decayed cavities in a child of equal or less than 6 years of age [35]. Other fungal pathogens aside *C. albicans* that cause yeast infections include *C. tropicalis* and *C. glabrata*. However, *C. albicans* is the most renowned amongst them all [31]. Several studies have been directed at understanding the cell surface of *C. albicans* mainly because of the two main functions of the cell surface which include shape maintenance of the fungus and secondly, the interaction of the fungi with its external environment which include its host [11]. The latter part of the function of the cell surface highlights the reason why most research is focused on the cell surface of *C. albicans*. The virulence attributes of *C. albicans* includes phenotypic switching, dimorphism, hyphal formation and secretion of extracellular hydrolytic enzyme which includes aspartyl proteinases which are also called aspartic proteinases [36], [37].

Secreted Aspartic Proteinases (SAPs) are known to be located at the surface of the cell. They are encoded by a multigene family which includes the presence of 10 SAP genes (SAP1-10)[38]–[42] which have been detected under many laboratory conditions[43]. Besides being among the virulence factors in Candidiasis, the activities of SAPs also contribute to tissue damage of the host, particularly SAP 1-3[44]. Removal of SAP1-6 have been suggested to assuage virulence in candidiasis keratitis [45]. Nevertheless, SAP1-10 are contributing factors when it comes to vaginal candidiasis[46], [47]. The activities of SAP depend on pH, SAP1-3 are more active in lower pH(3-5) while SAP4-6 are more active at higher pH values (5-7)[32]. Though the normal pH of blood is neutral (7.4). However, the pH values vary through the body, such as the vagina area which is more acidic and the oral cavities which is neutral. Hence, the reasons why some SAP thrive more in certain areas of the body[32]. Since, SAPs play a major role in many stages of infection of candidiasis, this makes it a potential drug target for treating Candidiasis infections[48], [49]. Pepstatin A has been used to inhibit SAPs[11]. However, there is need for new SAP inhibitors as there are new pathogenic fungal species, antifungal resistance, drug interactions and bioavailability amongst many other factors[48].

Azole based compounds alongside, polyenes are the most popular anti-fungal drugs used in treating candida infections[50]. However, polyenes have shown to be toxic hence the decrease in their use in treating candidiasis as compared to azole based compounds which are much safer[51]. Amphotericin B (AMB) is the most popular amongst the polyenes primarily because of the low occurrence of fungal resistance against it. However, it is nephrotoxic[50]. The known mode of action of antifungal drugs is to target the cell wall or membranes of the pathogen[10]. Hence the polyenes bind to ergosterol, the major sterol

of fungal membranes while the azoles inhibit of the fungal cytochrome P450-dependent lanosterol-14- $\alpha$ -demethylase which consequently leads to ergosterol reduction[16], [50], [51]. This action makes the membrane permeability and consequently leads to the disruption of enzyme systems bound to the membrane[52]. However, recent studies have shown that SAPs contribution to *C.albicans* virulence and hence are a potential drug target[31], [44], [53]. Many azole compounds have been designed over the years to improve the treatment of candidiasis. Ketoconazole proved to have superior in vivo activity and lower degree of inactivation after being absorbed as compared to other azole antifungal drugs such as clotrimazole[54]. Ketoconazole is also the only known antifungal drug to bind to the androgen receptor[55], [56]. Fluconazole and Itraconazole are also proven to be more effective than Clotrimazole and Nystatin(a polyene) when it comes to treating oropharyngeal candidiasis[57]. However, Clotrimazole has also shown to be successful in treating vaginal candidiasis as compared to the popular polyenes (AMB and Nystatin). Nevertheless a demerit of Clotrimazole is its side effect neurological reactions and gastrointestinal troubles[58]. Itraconazole is very active against mucosal form of candidiasis and it is quite similar to Fluconazole with respect to its activity. However, the latter has different pharmacological properties and does not violate any of the Lipinski's rule of five (RO5)[59], [60] alongside voriconazole[61], [62]. Azole based compounds have also recently been applied in corrosion inhibition[63] and Surface Enhanced Raman Spectroscopy (SERS)[64], [65].

## **2.2 Resorcinol**

Resorcinol (1,3-dihydroxybenzene) is an important building block in organic synthesis and finds several applications in pure and applied fields of science [66], [67]. Because of

its pharmacological and biological importance, in particular its use as a potent antibacterial agent [68], resorcinol has been a subject of extensive interest both from experimental and theoretical points of view [22]. In the solid and gas phases, three possible rotamers of resorcinol are known (Scheme 1).

**Scheme 1.** Atom numbering and the three possible rotamers of resorcinol

In case of solid-phase resorcinol, intermolecular interactions are stronger, which is due to solid packing arrangement. Based on x-ray crystallographic analysis, resorcinol exists in two forms i.e.,  $\alpha$ - and  $\beta$ -resorcinol. The crystal structure of  $\alpha$ -resorcinol, the stable form at the room temperature and atmospheric pressure, was first reported by Robertson [69]. The study revealed that molecules in  $\alpha$ -resorcinol maintain the anti-configuration (**A**) of  $C_{2v}$  symmetry [69]. The crystal phase structure of  $\alpha$ -resorcinol is stabilized by intermolecular hydrogen bonding with a distance in the order of 2.7 Å. Two years later, the crystal structure of  $\beta$ -resorcinol, which arose due to phase change at 347 K, was also disclosed [70]. In the case of  $\beta$ -resorcinol, the molecular conformation interconverts into the  $C_s$  anti-syn (**AS**) configuration.  $\beta$ -Resorcinol was shown to have a denser phase with a nearly 3% volume contraction [70]. In both systems ( $\alpha$  &  $\beta$ -resorcinols), the unit cell contains four resorcinol molecules with different molecular packing and lattice parameters [22], [69]. Raman

spectroscopy has been used to characterize the  $\alpha$  to  $\beta$  phase change and study different nature of intermolecular hydrogen bonding networking as the resorcinol changes from one crystalline phase to another [70], [71].

Moreover, studying the properties of the three possible rotamers of resorcinol in the gas phase has been of great interest. In previously reported spectroscopic studies, anti-syn (**AS**) and anti (**A**) rotamers were readily identified due to their comparable stabilities. The free-jet spectrum of resorcinol with only a single origin in the near-UV region was first disclosed in 1950 [72]. This was followed by a report by Dunn *et al* [72] on high-resolution laser resonant two-photon ionization (R2PI) spectra of resorcinol, which permitted the identification of three distinct rotamers of the compound. The resonance-enhanced multiphoton ionization (REMPI) and hole-burning (HB) spectra of resorcinol were also recorded by Gerhards *et al* [73] wherein both **AS** and **A** rotamers were identified. In 1996, Melandri *et al* [74] confirmed the coexistence of the three configurations of the compound in the gas phase by free-jet millimeter wave (MW) spectrum [75]. The study revealed that **A** and **AS** forms possess relatively similar stability whereas the **S** form lies at least  $400\text{ cm}^{-1}$  higher in energy. The careful assignments of the vibronic states in the dispersed fluorescence (DF) spectra of resorcinol confirmed the presence of the more stable **A** and **AS** forms although there was a little variance in the spectral features between the two rotamers [76]. Moreover, the **A** and **AS** rotamers of resorcinol and its deuterated analogs in their  $S_0$  and  $S_1$  electronic states were also confirmed by the high-resolution UV spectroscopy [75]. However, the study did not cover investigation of the **S** rotamer. In the same study [75], automated assignments have been performed using a genetic algorithm approach with an asymmetric rotor Hamiltonian. Later, Gerhards *et al* [76] have reported the mass analyzed threshold ionization

(MATI) and infra-red photo induced Rydberg ionization (IR-PIRI) spectra of resorcinol and its cationic species wherein they observed the **A** and **AS** conformers of the compound (Claudio and Ha, 1990; Gerhards et al., 1998). Thus, it can be concluded that the **AS** and **A** forms of resorcinol are more stable in the gas phase compared to the **S** form. These findings were further supplemented by theoretical calculations together with some of the aforementioned structural and conformational spectroscopic investigations [76]–[78]. Additional computational studies on the energetics and structural properties of resorcinol have also been reported [77]. The predicted energy differences between the three isomers (**AS**, **A** and **S**) of resorcinol at the HF/4-31G\* level was found to be smaller (0, 84 and 378 cm<sup>-1</sup>, respectively) with a rotational barrier around the C-OH bond in the order of 2-3 kcal/mol [78]. Computational studies have been extended to the crystal phase of resorcinol. The crystal morphology and solvent effect on the crystal habit of resorcinol and other organic systems by *ab initio* calculations were studied [79]. Moreover, the stability and lattice parameters of the two crystalline phases of resorcinol were explored by molecular dynamics calculations in an NPT ensemble [80], showing good agreement between the predicted properties and experimental data earlier reported. Moreover, theoretical methods have been employed to understand the nature of interaction between resorcinol and different solvents [81]–[83]. Blanco et al have explained the overlapping  $pK_a$  values of resorcinol determined by UV-Vis spectroscopic techniques with the help of HF and DFT-B3LYP calculations [84]. The theoretical data enabled to explore the molecular conformations and solute–solvent interactions of the resorcinate anions. Moreover, B3LYP method was employed [85] to interpret the solvation effect by predicting total energies, dipole moments, reactivity parameters and transition states involved in resorcinol-solvent species. A theoretical

resorcinol-water model of 1:2 stoichiometry was investigated to explain the high dipole moment (8.6 D) of resorcinol in water [85].

The assignments of the vibrational modes of resorcinol in crystal and gaseous phases by a number of spectroscopic techniques were also carried out, which provided deeper understanding of the electronic and rotameric nature of resorcinol. The vibrational assignments based on its infrared and Raman spectra in the solid phase were first reported by Penot *et al* [81] and Hidalgo *et al* [82]. Later on, a number of these assignments were revised by Green *et al* [83]. The gas-phase infrared spectrum of resorcinol in the range 4000-625  $\text{cm}^{-1}$  at 190°C was recorded by Wilson [86]. Detailed assignments of the IR bands revealed that the single molecule adopts a  $C_s$  symmetry structure that corresponds to the **AS** rotamer. In a recent gas-phase study [87], the analysis of the vibrational states by the dispersed fluorescence (DF) spectrum of resorcinol in the free jet revealed the coexistence of **AS** and **A** rotamers. Moreover, the polarized infrared spectrum of  $\alpha$ -resorcinol crystals in the lattice mode and internal vibration regions at lower temperatures have been reported [88]. Particularly, O-H stretching frequencies have been investigated by means of infrared photo induced Rydberg ionization (IR-PIRI) [89] and non-resonant ionization detected (NID) infrared and near-infrared (IR-NIR) spectroscopic techniques [78]. The assignments of the  $\nu_{\text{OH}}$  stretching overtones of resorcinol clearly confirmed the existence of the two nonequivalent O-H bonds associated with the **AS** rotamer. In addition, the other two rotamers could also be assigned in the overtone spectra with the help of harmonic oscillator local mode calculations performed at the B3LYP/6-311++G(3df,2pd) level [89].

Herein, we wish to report our study based on extensive vibrational frequency calculations based on both the single molecule and unit-cell system of crystalline resorcinol. The infrared, Raman and  $^1\text{H}$  NMR analyses of resorcinol-OD and resorcinol dianion salt have also been performed and compared with the resorcinol. The conformation of resorcinol has been explored at different calculation levels for a more accurate energetic description and to achieve reliable understanding of the molecular docking mechanism towards keratin-7.

## CHAPTER 3

### METHODOLOGY

#### 3.1 Experimental Details

The studied of clotrimazole and resorcinol were purchased from Sigma Aldrich and used without any additional refinement for spectroscopic analyses. The mid-infrared spectra ( $4000\text{--}400\text{ cm}^{-1}$ ) were collected at room temperature using a Nicolet 6700 FT-IR spectrometer equipped with a globar source, a KBr beam splitter, and a DTGS KBr detector at one-wavenumber resolution using a KBr window. The Nicolet 6700NXR FT-Raman module equipped with a CaF<sub>2</sub> beam-splitter and an InGaAs detector was used to collect the Raman spectra ( $4000\text{--}100\text{ cm}^{-1}$ ) of the three compounds at room temperature. The He-Ne laser source operating at 1064nm with 0.2 W was used for sample excitation.

#### 3.2 Computational Details

All the computational calculations of the studied molecules were done with the Gaussian 09 program [90] using the Density Functional Theory. The molecules were optimized at the B3LYP method using the 6-311++G(d,p) as the basis set. The vibrational frequencies were calculated for all the studied molecules and no imaginary frequencies were present. The VEDA program [91] alongside GaussView [92] were used to assign the vibrations of all the molecules. The frequencies calculated were scaled to have a reasonable comparison with the experimentally determined ones using the method developed by Saadi and Laane [93]. Frequencies within the range of  $2700\text{ cm}^{-1}$  and  $4000\text{ cm}^{-1}$  used a scaling factor of 0.961 while those within the range of 0 to  $1800\text{ cm}^{-1}$  used 0.985 as the scaling factor. The proteins structures were downloaded from the protein data bank (PDB) [94] and were

validates using Ramachandran plots via the Moleman 2 program [95]. All the molecular docking studies were calculates using the CLC drug discovery workbench 3.0.2 [96]and the molecular interactions were viewed using Discovery studio [97].

## CHAPTER 4

### RESULTS AND CONCLUSION

#### 4.1 Clotrimazole

##### 4.1.1 Molecular structure

CTZ is a non-planar compound that contains 4 ring structures which include two benzene rings, a chlorobenzene and an imidazole ring. The four rings are connected by a quaternary carbon at the center as seen in Fig.1 which gave the structure a  $C_1$  symmetry point group. Song and Shin [1] had described the crystal structure of CTZ. The Potential Energy Surface (PES) Scans depicted in Figs 5 and 6 showed rotations around the  $C_6-C_7$  and  $C_7-N_{10}$  bonds respectively. The PES resulted in four energy conformations; A B and C (Fig. 2). It was observed that CTZ had low stability whenever the chlorine atom was close to any of the aromatic rings as seen in conformers A and C (Figs. 3 and 4). This might be due to steric crowding which also involves the repulsion between the negative electrons of the chlorine atom and the pi-electrons present in the aromatic rings and hence the most stable structure conformation occurred when the rings were most far apart (conformer B) to minimize repulsion. The energy difference between the most stable conformer and the least unstable conformers is about 5kcal/mol. In the first PES scan (Fig. 3) which has  $C_6-C_7$  has its rotational bond, it was observed that the chlorobenzene moved about  $180^\circ$  from conformers A to B. The relative energy difference was about 5kcal/mol though the energy. However, in the second PES scan (Fig. 4) which has its rotational bond at  $C_7-N_{10}$ , it was observed that a  $180^\circ$  flip in the imidazole ring from conformer A led to a lower energy conformer C which had a relative energy difference of less than 1kcal/mol. The PES was also carried out in aqueous phase and

the results showed the same conformations as in gas phase except that the energies were slightly higher (Table 1). Hence, CTZ is less stable in aqueous phase than in gas phase. The PES revealed Conformer B has the most stable while conformer A and C had similar stabilities. Conformer B's stability is due to the absence of steric crowding and repulsive effect between the chlorine atom and the benzene ring.

**Figure 1.** The optimized geometry (DFT) of CTZ

**Figure 2.** The three possible minimal energy conformations of CTZ

**Figure 3.** Potential energy scan resulting from the rotation about the  $C_1-C_6-C_7-N_{10}$  bond as calculated at the B3LYP/6-311++G (d,p) level of theory.

**Figure 4.** Potential energy scan resulting from the rotation about the C<sub>6</sub>-C<sub>7</sub>-N<sub>10</sub>-C<sub>25</sub> bond as calculated at the B3LYP/6-311++G(d,p) level of theory.

**Table 1.** The relative energies from the three possible conformers of clotrimazole in gas and aqueous phases.

Conformers	Gas phase (kcal/mol)	Aqueous phase (Kcal/mol)
A	5.195	5.265
B	0.000	0.000
C	4.808	4.958

#### 4.1.2 Geometrical parameters

The bond angle and bond distances of the chlorobenzene and imidazole ring were used as the selected parameters in CTZ and were compared to other reported works. The bond length of the chlorobenzene ring (Table 2) showed a good agreement between the XRD [1] and the DFT. The C<sub>11</sub>-C<sub>1</sub> which is the longest bond length was 1.743 and 1.764 for both XRD and DFT respectively. This was also in agreement to the single molecule of chlorobenzene which was determined experimentally to be 1.725 by Roussy et al [98] and theoretically calculated to be 1.762 [99], though at a lower basis set of 6-311G\* as compared to the 6-311++G(d,p) basis set used in this work. The bond angle C<sub>2</sub>-C<sub>1</sub>-Cl<sub>11</sub> was depicted to be 116° and 115.4° for the XRD and DFT respectively and this was lower compared to the single chlorobenzene molecule which was 119.801° and 119.308° for both the experimentally observed [98] and DFT calculated [99] respectively. The difference in bond angle is possibly due to the orientation of the chlorine atom to minimize the steric crowding due to the presence of the other three aromatic rings present in the title compound. For the imidazole ring, the DFT calculated bond lengths were slight higher than

the XRD. However, there was a very good agreement between N<sub>12</sub>-C<sub>24</sub> and N<sub>12</sub>-C<sub>25</sub> which were 1.372 and 1.315 respectively for the XRD and 1.375 and 1.314 for the DFT calculated. This also concurred to the experimental data [100] of single imidazole molecule and theoretically calculated [99] (though at a lower basis set of 6-311G\*\*) which gave 1.314 and 1.312 respectively for N<sub>12</sub>-C<sub>25</sub>. The bond angles N<sub>10</sub>-C<sub>23</sub>-C<sub>24</sub> and N<sub>10</sub>-C<sub>25</sub>-N<sub>12</sub> had a perfect agreement in both the XRD and DFT of 106.1° for the former and a very good agreement of 112.5° and 112.3° for the latter respectively. This also concurred to the single imidazole theoretically calculated which gave 105.072° and 111.650° for N<sub>10</sub>-C<sub>23</sub>-C<sub>24</sub> and N<sub>10</sub>-C<sub>25</sub>-N<sub>12</sub> respectively.

**Table 2. Some selected structural parameters of clotrimazole calculated using DFT/B3LYP at the 6311++G(d,p) basis set with XRD data.**

Label	XRD	DFT

### 4.1.3 IR and Raman Spectra

The experimental Raman and IR bands (Figs 5 and 6) along with the calculated wavenumbers are depicted in Table 3. The wavenumbers were scaled using a factor of 0.961 for frequencies greater than  $2700\text{ cm}^{-1}$  and 0.985 for frequencies less than  $1800\text{ cm}^{-1}$  [93]. CTZ has 42 atoms and hence using the  $3N-6$  formula for the degree of freedom for a non-linear molecule, where  $N$  is the number of atoms it has 120 vibrational modes. The peak at  $3302\text{ cm}^{-1}$  are -CH stretch vibrations. This is because the vibration is symmetric and hence has a low activity in IR spectroscopy whereas it is highly active in Raman spectroscopy. The imidazole ring in CTZ has no N-H vibrations since the first Nitrogen atom is bonded to the quaternary carbon while the other is contributing to the aromaticity of the ring. The C-N stretch has been experimentally reported in imidazole to be in  $1325\text{ cm}^{-1}$  to  $1486\text{ cm}^{-1}$  [101] whereas it is observed to be in be at  $1478\text{ cm}^{-1}$  and calculated to be at  $1476\text{ cm}^{-1}$ . The difference in frequency is probably because of the quaternary carbon attached to the Nitrogen atom. The imidazole ring deformation was reported by Ramasamy to be at  $891\text{ cm}^{-1}$  and  $899\text{ cm}^{-1}$  for observed and calculated respectively [101]. However, in CTZ the imidazole ring deformation was seen at  $883\text{ cm}^{-1}$  and  $901\text{ cm}^{-1}$  for both observed and calculated respectively. The C-H stretch has been reported to be in the range of  $3001\text{--}3091\text{ cm}^{-1}$  for Toluene [102]. Nevertheless, in CTZ the range is  $3040\text{--}3173\text{ cm}^{-1}$  for the two benzene rings. However, at both  $1156\text{ cm}^{-1}$  and  $1145\text{ cm}^{-1}$  for both observed and calculated respectively, a C-H ring stretch is common to the three benzene derivatives simultaneously. The C-C ring stretch in Toluene is stated to be  $1487\text{--}1624\text{ cm}^{-1}$  [102] while in CTZ it is observed to be in  $1472\text{--}1613\text{ cm}^{-1}$  for the two benzene rings. The chlorobenzene ring is responsible for the frequency observed at  $1617\text{ cm}^{-1}$ . The ring deformation for the two benzene rings occurs at  $1001$  and  $1002\text{ cm}^{-1}$  for both observed and calculated respectively this is much lower compared to what was reported for by Ramasamy

et al for Toluene [102] which occurs at 1032 and 1042  $\text{cm}^{-1}$  for both observed and calculated respectively. The frequency seen at 1036  $\text{cm}^{-1}$  is exclusively for the ring deformation of chlorobenzene. The Cl-C stretch was seen at 438, 434 and 447  $\text{cm}^{-1}$  for the calculated, and experimentally determined IR and Raman respectively.

#### 4.1.4 Frontier molecular orbitals

The HOMO (Highest Occupied Molecular Orbital) and LUMO (Lowest Unoccupied Molecular Orbital) are collectively known as the FMO (Frontier Molecular Orbital). They are an important quantum chemical parameter which help in understanding the bonding and adsorption properties of a compound especially when it comes to the use of compounds as corrosion inhibitors. The energy of the HOMO relates to ability of a compound to bind to a metal surface. A high HOMO energy indicates a good electron donation ability while a small HOMO-LUMO gap encourages the donation between the molecular orbitals of the compound and the orbitals of the metal surface such that a high adsorption will be detected [103]. The FMO values for CTZ are -6.155 eV and -1.277 eV for the HOMO and LUMO respectively while the energy band gap is 4.878 eV. It is observed that the HOMO occurs in the imidazole ring and this is mainly due to the presence of the nitrogen atoms while the LUMO occurs on the benzene rings which is due to the pi-electrons (Fig. 7). The FMO results indicated that CTZ has a good potential as a corrosion inhibitor and this has been reported in its ability to reduce the corrosion rate of Aluminum [63], [104].

**Figure 7. The HOMO (A) and LUMO (B) maps of CTZ**

#### **4.1.5 Molecular Electrostatic Potential**

The Molecular electrostatic potential (MEP) map indicates the charge distribution in a molecule which is useful in knowing the potential sites for nucleophilic and electrophilic attacks. The blue region is positive and indicates nucleophilic reactivity while the red and yellow regions are negative and denote electrophilic reactivity. The electronegative regions occurred on N<sub>12</sub> of the imidazole ring (red) and the chlorine atom (light yellow) though the former is more electronegative while the blue region occurred on the hydrogen atoms of the benzene rings (Fig. 8). The most reactive region of CTZ occurred on the nitrogen atom of the imidazole ring.

**Figure 8.** The MEP map of CTZ

#### 4.1.6 Molecular docking studies

Recent studies [44], [45], [49], [105]–[107] suggest that secreted aspartic proteinases (SAPs), particularly SAPs 1-10 are virulent proteins which play an important role in the infection caused by *C. albicans* and hence should also be a drug target. These proteins are mostly found in the cell membrane [32] which implies they can easily interact with the host cells. Unfortunately, most of the crystal structure of the SAP proteins are not available in the protein database. For this study, the SAP2 protein was used with PDB ID: 1EAG [108]. Docking, which is the technique that predicts the best possible orientation known as a pose by which a ligand (drug) can interact a protein to form a steady complex [109]. This method is relatively new as it is one of the Computer Aided Drug Design (CADD) methods and it has also been used in the study of CTZ with CYP121 of another pathogen responsible for Tuberculosis, *Mycobacterium tuberculosis* [110]. MOLEMAN 2 was used to validate the target protein (SAP2) using Ramachandran plot (Fig. 9b). For a protein to be valid, it is recommended that the outlier percentage does not exceed 5% [111]. The outlier percentage of the target protein was detected to be 2.6% and hence was valid to be used for molecular docking analysis. The CLC drug discovery workbench program [96] was used for the molecular docking studies. The optimized structure of all the three conformers from Gaussian 09 were used as the ligand input file for the docking process while the complex A70450 present in the initial structure of the target protein was set as the reference ligand to establish the binding site (Fig. 9a) which gave the following binding parameters; 41.480, 22.670 and 12.460 for the X,Y and Z axes respectively. All the water molecules and ligand present in the initial structure were all removed from the target protein before docking the ligands and the docking was done with a radius of 13 Å in the binding site. The total docking score is a sum of the Hydrogen Bond (HB), Steric Interaction (SI) and ligand

Conformation Penalty (LCP) score values. All the three possible conformers showed good binding scores since they all had negative values when bound to the target protein. The steric interaction score had the highest contribution to the final docking score. Though, there was no significant difference in their score values (Table 4). The Drug discovery studio program [97] was used to visualize the binding mode and molecular interactions of CTZ with the target protein. However, since they all had similar docking scores only the binding mode of conformer B which is the most stable was depicted (Fig. 10). The molecular interactions of CTZ with the target protein includes two carbon-hydrogen bonds with SER 118 and ASP 120; Pi-alkyl interactions with ILE 30, ILE 119 and ILE 123; Pi-pi T-shaped interaction with TYR 84 and Pi-anion with ASP 120.

#### 4.1.7 Conclusion

DFT studies using potential energy scan gave rise to three possible conformations of clotrimazole in both gas and aqueous phases. Extensive vibrational analysis was done to assign the spectroscopic bands. The molecular electrostatic map indicated that the positive region around the benzene rings while the negative region occurred on the imidazole ring. The frontier molecular orbitals revealed that the HOMO occurred on the imidazole ring while the LUMO occurred on the benzene rings. Molecular docking showed that all the possible conformers had good binding affinities with the target protein (SAP2). The molecular interactions include hydrogen bonding and steric interactions with the amino residues TYR, ASP and ILE present in the binding site. This molecular interactions could provide insight to the mode of action in which CTZ acts on *C.albicans* in treating candidiasis.

## 4.2 Resorcinol

### 4.2.1 Structure and vibrational properties

All theoretical levels employed in this study have predicted consistently that **AS** is the most stable form which is around 0.2 and 0.7 kcal/mol more stable than **A** and **S** forms, respectively. The prediction on the rotational constants with respect to the x, y and z coordinates are also in excellent agreement with experimental values (Table 6). Whereas the B3LYP level predicted the existence of three rotamers strictly planar with no imaginary frequencies, free-of-symmetry-constrain more accurate MP2 and MP4 optimizations predicted the hydroxyl group to very slightly tilt from the plane of the molecule. Like phenol, resorcinol in its electronic ground state adopts a planar configuration as it keeps the oxygen lone pairs of electrons in a position encountering the least possible intramolecular repulsion. The rotational barrier around the C-O bond predicted from the MP2 and B3LYP levels was found to be 3.5 and 3.8 kcal/mol, respectively.

To attain a better understanding of the nature of the intermolecular hydrogen bonding in the crystal phase of resorcinol and the bioactivity of the resorcinol molecule towards the target protein, we focused on the conformational properties arising particularly from the internal rotation by the two hydroxyl groups. The derived PES scan (Fig. 14) in terms of both CC-OH dihedral angles (denoted as  $\varphi_1$  and  $\varphi_2$ ) revealed that in non-condensed phases resorcinol molecule interchanges from one form into another through the **AS** route, i.e., in the **AS**  $\leftrightarrow$  **A**  $\leftrightarrow$  **AS** or **AS**  $\leftrightarrow$  **S**  $\leftrightarrow$  **AS** interchange patterns. On the other hand, at least 7 kcal/mol is required for the **A**  $\leftrightarrow$  **S**  $\leftrightarrow$  **A** or **S**  $\leftrightarrow$  **A**  $\leftrightarrow$  **S** types of conformational interchange which is less likely to take place. The MP2/6-311++G(d,p) characterized the

three possible minimum forms to be more flat than that predicted by the B3LYP/6-311++G(d,p) level of theory. This supported the assumption that the molecule in the solid lattice is capable of adopting an internal arrangement that maximizes the extent of the intermolecular hydrogen bonding, whose influence in turn can be clearly observed from its high melting point and low solubility. The structural parameters of the optimized unit cell of  $\alpha$ -resorcinol were in good agreement with those have been determined by the x-ray experiment [112] Furthermore, the unit cell (Fig. 11) adopts an overall near  $C_s$  symmetry, wherein some of the hydroxyl groups tend to deviate from planarity (Table 7) to facilitate O-H...O intermolecular bonding. The difference between the calculated non-bonded H...O distances (in the order of 1.9 Å) and that reported experimentally (1.7 Å [112]) implies the very strong packing forces facilitated by intermolecular hydrogen bonding in resorcinol.

The comparison between the calculated B3LYP/6-311++G(d,p) and the experimental (gas [10] and solid [32]) bond lengths, bond angles and dihedral angles of the most stables forms of resorcinol (anti **A** and anti-**syn AS**), its dianion salt and the  $\alpha$ -unit cell has been listed in Table 7. The bond lengths and most of the bond angles do not vary much between the two rotameric forms, nor deviate much from those reported for the solid phase. The changes of the structural properties for the benzene ring in going from resorcinol to its dianion salt are quite interesting and some insights could be noticed by carefully comparing the obtained computational and spectroscopic data. The aromatic C-C bonds in the dianion salt were predicted to be in average 0.05 Å longer than compared to the parent molecule. The transformation to the dianion form makes the electron pairs on oxygen tend to delocalize more, resulting in the development of a trace  $\pi$ -character across the C-O bonds, which in turn distort the uniformity of the electron density of the benzene

ring. This can be viewed from the variation in the calculated C-C bond distances and CCC angles as well as from the lesser  $sp^2$  character depicted by the deviation of the hydrogen atoms from the planar configuration. The observed shifts in the infrared and Raman spectral bands associated with the ring and C-O modes (Tables 8-10) support the calculation findings and are clarified further in the next section. The  $^1\text{H}$  NMR data support the structural influence of abstracting the hydroxyl hydrogens from the resorcinol ring. The resonance peak at  $\delta$  4.72 ppm due to hydrogen of hydroxyl function in resorcinol disappeared in both resorcinol-OD and dianion. In addition, the aromatic signals in dianion exhibited slight upfield shift compared to parent compound. This was indicative of electron shielding effect due to increased flux of electron density from oxygen lone pairs into the aromatic ring.

The assignments of local vibrational modes of resorcinol, its deuterated isotopomer and dianion salt derivatives in the solid phase were given in Tables 3-5. While a number of reports had proposed the vibrational assignments of resorcinol in the condensed and gas phases [6, 11,13,15,24,25,26,29] , the assignments presented here were made on a comparative basis with resorcinol derivatives. An overview of the previous infrared and Raman vibrational assignment reports [76] performed on resorcinol showed that most of the features of the solid-phase and gas-phase spectra are of high similarities. In the current study, the assignments of vibrational modes associated with the hydroxyl groups were affirmed by monitoring the isotopic shifts in the spectra the -OD isotopomer and the disappearance of such modes in the dianion salt spectra, supported by theoretical frequencies. To insure more reliable assignments and account for possible intermolecular interactions, the infrared and Raman wavenumbers of  $\alpha$ -resorcinol and its -OD derivative

were compared with the calculated ones for the optimized unit cell structure (Tables 8 and 9).

The 36 vibrational modes in resorcinol and its -OD derivative, which adopt  $C_{2v}$  symmetry for the **A** form, span the irreducible representations:  $13 A_1 + 4 A_2 + 12 B_1 + 7 B_2$ , while in the case of the dianion salt, due the absence of the two alcoholic hydrogens, there are 30 vibrational modes that span the irreducible representations:  $11 A_1 + 3 A_2 + 10 B_1 + 6 B_2$ . According to the symmetry selection rules  $A_2$  modes are expected to be only Raman active. However, since in the solid phase resorcinol was reported [33] and calculated at the MP2 and MP4 levels to be slightly non-planar, some of the  $A_2$ -symmetry modes, namely  $\nu_{14}$  and  $\nu_{15}$ , absorb very weakly in the infrared spectra. Such modes, however, could be located for the dianion salt only in the Raman spectrum due to its strictly planar configuration. Calculated frequencies for single molecules agree in most of the cases with those experimentally observed in the solid phase vibrational spectra. However, the values of some of the computed frequencies were noticed to be smaller than the corresponding observed ones. These vibrations belong mainly to  $A_2$  and  $B_1$  symmetries which describe out-of-plane modes. The higher experimental values of the solid phase facilitated by strong packing forces are somehow due to hindrance of out-of-plane vibrations and hence requires slightly greater vibrational energies. This motivated us to recalculate the vibrational frequencies for  $\alpha$ -resorcinol (rotamer **A**) but in the environment of the unit cell (Fig. 11) rather than a single molecule. The deviated frequencies in the case of the isolated molecular system were improved and showed better agreement with experimental values of the solid phase especially for the bending modes below  $1000\text{ cm}^{-1}$  (Tables 8 and 9). For instance, the O-H wagging (O-D wagging for the OD isotopomer) mode,  $\nu_{16}$ , were calculated to be

in the range of 337-350  $\text{cm}^{-1}$  (250-252  $\text{cm}^{-1}$ ) in the case of unit cell and 304  $\text{cm}^{-1}$  (219  $\text{cm}^{-1}$ ) for isolated molecules, compared to the observed 358  $\text{cm}^{-1}$  (249  $\text{cm}^{-1}$ ) values.

The observed broad infrared band nearly at 3180  $\text{cm}^{-1}$  which is associated with the stretching modes of the intermolecular hydrogen-bonded –OH group was shifted upon deuteration down to 2387  $\text{cm}^{-1}$  with the band pattern and intensity being retained indicating the existence of appreciable hydrogen bonding in the case of the isotopomer sample. The asymmetric and symmetric O-D stretching vibrations were resolved in the Raman spectrum as by the weak lines observed at 2452  $\text{cm}^{-1}$  and 3033  $\text{cm}^{-1}$ , respectively. The in-phase in-plane O-H wagging mode observed as a medium intensity infrared band at 1166  $\text{cm}^{-1}$  (DFT is 1188  $\text{cm}^{-1}$ ) in the resorcinol spectrum was shifted to 951  $\text{cm}^{-1}$  (DFT is 929  $\text{cm}^{-1}$ ) as a strong infrared band in the spectrum of the isotopomer derivative. The isotopic shifts associated with the hydroxyl groups in the solid phase and defined as  $\nu_{\text{Resorcinol}}/\nu_{\text{Resorcinol-OD}}$  were found to be greater for the stretching vibrations (1.33) compared to the bending ones (1.23) which could be attributed to the more significant involvement of the stretching modes in the hydrogen bonding compared to the corresponding bending ones.

Moreover, some vibrational frequency shifts were noticed because of the abstraction of the acidic protons from the resorcinol molecule (Figs. 12 and 13). The C-O in-phase ( $\nu_7$  at 1281  $\text{cm}^{-1}$  with 67% PED) and out-of-phase ( $\nu_{27}$  at 960  $\text{cm}^{-1}$  with 33% PED) were shifted to higher frequencies (1404 and 1236  $\text{cm}^{-1}$ , respectively) and become less coupled with other modes (75% calculated PED values). This is due, as indicated earlier, to the more pronounced  $\pi$ -electron character associated with the C-O bonds and hence shorter bond lengths in the case of the dianion salt. This is accompanied with non-uniformity of the electron cloud across the benzene ring as supported by noticeable downward shifts of

the observed wavenumbers for the C-C stretching as going from resorcinol to its dianion derivative. For instance, the ring breathing mode observed as the strongest Raman line at 998 cm<sup>-1</sup> for resorcinol has shifted to 977 cm<sup>-1</sup> in the Raman spectrum of the dianion salt (Fig. 13). This is also true for other ring stretching modes such as  $\nu_5$ ,  $\nu_6$ ,  $\nu_{20}$  and  $\nu_{21}$ . Optimized DFT structures (Table 7) predicted an average increase in the C-C bond distance from 1.40 to 1.45 Å, and a decrease in the C-O bond distance from 1.356 to 1.296 Å, in going from resorcinol to its dianion salt. In addition, the C-H bonds was shown to be slightly less stiff in the case of the dianion salt where they absorbed as low as 2978 cm<sup>-1</sup> in the infrared spectrum with excellent agreement with the theoretical values (Table 10).

\*\* See footnotes of Table 8 for abbreviations.

### 4.2.2 Molecular docking analysis

During the past decades resorcinol exhibited a number of medical applications, especially as it is used as a starting material to produce derivatives of Active Pharmaceutical Ingredients (API) for treating Alzheimer's disease, sickle cell anemia and alcoholism [22]. However, resorcinol itself has been also used as a topical agent in treating dermatological diseases such as eczema, acne and Hidradenitis Suppurativa (HS). Molecular docking is a useful tool used in structure-based drug design (SBDD) to predict binding affinities of an API with specific protein targets [30] that play a role in the pathology of a disease. Resorcinol possess keratolytic properties and hence is known to target the follicular keratin plug which is the initiation stage of several HS lesions [29]. Therefore, a molecular docking analysis is useful to provide insights on the modes of action of resorcinol in treating HS. The structure of the target protein, keratin-7, was obtained from the protein database bank with PDB ID-4XIF [113], and Ramachandran plot was carried out to validate its structure where target protein should maintain a Ramachandran outlier less than 5% [95]. The Ramachandran plot gave an outlier value of 2.769% which indicated a good quality protein which can be used to accomplish conclusive molecular docking scenarios.

The optimized structures of the three resorcinol rotamers (Scheme 1) were trailed for docking with keratin-7 (Fig. 15). The binding affinities in terms of score values of the generated pose structures of resorcinol after binding with the protein are listed in Table 11. The three conformers of resorcinol showed similar binding affinities towards keratin-7 indicating that the stable mode of action of resorcinol with the target protein is irrelevant of the rotameric form it undergoes. Moreover, the steric interactions were expected to play

the major role in the docking process compared to hydrogen bonding. Due to the small size of the resorcinol molecule, keratin-7 seems to be capable of availing sterically favored regions to accommodate stable protein-ligand binding. Steric interaction is made up of non-polar, polar to non-polar, repulsive interactions, etc. that other than hydrogen bonding interaction [96].

Docking analysis, moreover, showed that while hydrogen bonding is not the most significant factor compared to steric interaction as discussed above, yet it shows an appreciable contribution to the stable protein-ligand long-distance binding. For example, in the case of rotamer **AS**, the computed favorable possibilities included three different hydrogen bonding interactions represented in Fig. 16 and were carefully tracked. Due to their high electronegativity, the two oxygen atoms of resorcinol exhibited a significant role in the biological activity of the ligand towards keratin-7. The molecule of resorcinol acts as both a hydrogen bond donor and acceptor towards ASN 557 giving rise to a stable conventional hydrogen protein-ligand bonding. Non-conventional O...HC interaction between resorcinol and THR 809 with a calculated distance of 2.6 Å was also predicted [114]. On the other hand, a hydrophobic interaction of pi-alkyl type with LYS 898 is well-maintained within an approximation of 4.5 Å. These four interactions account for the binding affinity for **AS** and, with the remarkable facilitation of the steric factor, are responsible for the keratolytic properties of resorcinol with keratin. Other two rotamers also showed similar types of interaction resulting with comparable overall docking scores.

**Table 11.** Binding affinities of different conformers of resorcinol with Keratin (PDB ID: 4XIF)

**Figure 15.** The tertiary structure of keratin-7 (PDB ID -4XIF). The binding site is indicated with a yellow sphere.

**Figure 16.** (a) The binding modes, and (b) molecular interactions of AS rotamer with the amino residues of keratin-7 (PDB ID: 4XIF). Interactions labelled as green, red and purple refer to hydrogen-bonding, carbon-hydrogen, and  $\pi$ -alkyl types of interaction, respectively. Bond distances are given in Å.

### 4.2.3 Conclusion

The B3LYP/6-311++G(d,p) computational method was utilized to optimize the unit cell of the crystal structure of  $\alpha$ -resorcinol and to calculate the associated harmonic frequencies helped in understanding some spectroscopic differences in the infrared and Raman spectra between the solid and the gas phases. The potential energy distribution of the normal vibrational modes was done using the VEDA program. The AS rotamer is the most stable and also was the best pose in which the resorcinol molecule bound to the target protein keratin-7(PDB-4XIF) in the molecular docking analysis which gave an insight to the keratolytic property of resorcinol in HS lesions.

## 4.3 Molecular Docking of other Bioactive compounds

### 4.3.1 Molecular Docking of MNPE

The validation of the structure of the target protein is an essential step in the drug discovery process [115]. The crystal structure of a human GABA receptor (PDB ID: 4COF) shown in Fig. 10a was done at a resolution of 2.97 Å and was used as the target protein [116]. The target protein contains 5 possible binding sites, namely chains A, B, C, D and E. Each chain is consisted of about five  $\alpha$ -helices which are spiral in shape and about 8  $\beta$ -pleated sheets. Ramachandran plot (Fig. 17b) checked a total number of 1574 residues out of the 1665 amino residues present in the target protein, which is tantamount to about 95% of the total residues. The total number of core regions and outliers are 1546 and 28 respectively, which gave a rise to a percentage outlier of 1.8 %. The Ramachandran plot uses percentage outlier to ascertain the validity of a protein structure. The recommended range for the percentage outlier for a valid protein structure is between 0 to 5 % [95]. Hence, the target protein (PDB ID: 4COF) used for the molecular docking was valid. The five binding sites of the

benzamidinium molecule, A, B, C, D and E, complexed with the crystal structure of the target protein (PDB ID: 4COF) were used for docking analysis. Benzamidinium is an agonist for the human GABA receptor [116] and hence its binding site was used as a reference for the molecular docking analysis. Table 12 lists the molecular docking results of (4-(3-methoxy-4-nitrophenyl)piperazin-1-yl)ethanone (MNPE) and human GABA receptor. Binding site C which is the reference site for BEN C in the original crystal structure had the highest total docking score value which implies that MNPE exhibits the best binding affinity towards the target protein within this binding site. The total score value is the sum of the Hydrogen Bond (HB) score, the Steric Interaction (SI) score and the ligand penalty conformation. It was also predicted that the ligand in binding site C has the lowest ligand conformation penalty value (7.910) and the most negative steric interaction score (-59.781) among the different binding sites. Four types of favorable interactions (Fig. 18) between MNPE and the target protein could be established. The favorable interactions between MNPE and the target protein included conventional hydrogen bonding with amino acids THR 202 and GLN 64,  $\pi$ - $\pi$  stacking and  $\pi$ -alkyl interactions with PHE 200, TYR 62 and TYR 205, and carbon hydrogen bond with ASP 43 and TYR 157 (Fig. 18). The molecular docking analysis involved the generation of five low energy conformational scenarios known as poses. Unlike regular conformations, a pose structure is dependent on the target protein. Each pose was screened against the target protein in each of the five binding sites, A thru E. The binding mode conformation of MNPE in a binding site C have shown the best binding affinity (Fig. 18). During molecular docking analysis, the molecule orientated itself such that there exists an intramolecular hydrogen bonding between one of the hydrogens of the piperazine ring and the oxygen of the carbonyl group. The comparison

between the most stable conformer (B4) and the best binding pose from the molecular docking analysis is depicted in Fig. 19. It was evident that the docked pose and most stable conformer of MNPE were similar with respect to the position of the various functional groups except that the structure of the binding pose is contracted due to the presence of intramolecular hydrogen bonding along with its orientation of the flexible bonds in the molecule. The difference in the structure of the binding pose arises because in molecular docking the molecule would orientate itself such that it best-fit into the binding pocket of the target protein to ensure adequate binding.

**Table 12:** The docking results of the title compound with the human GABA receptor.

Binding Sites	HB score	SI score	Ligand conformation penalty	Total Score
A	-6.000	-53.167	6.611	-52.556
B	-5.513	-52.730	6.671	-51.572
C	-6.596	-59.781	7.910	-58.468
D	-8.628	-51.792	6.624	-53.795
E	-5.886	-53.699	6.687	-52.898

### **4.3.2 Molecular Docking of Gold Complexes**

The inhibition of thyroxine (TrxR) is important as a chemotherapeutic treatment, especially with the use of gold and platinum complexes especially the former which has been noted to be responsible in enzyme activity inhibition [117]. However, selenium has also proved to be useful in cancer treatment[118], [119]. Hence, the choice of docking the synthesized gold(1) complexes which all contain selenium with the target protein, thioredoxin reductase (PDB ID: 3EAN) [120]. The protein was validated using the Ramachandran plot with the Moleman 2 [95] to check for the percentage outlier. For a valid protein, the percentage outlier should be between the range of 0 to 5 % [95]. The target protein proved to be valid by having a percentage outlier of 2.7 %.

**Table 13.** The docking results of gold(I) complexes (1-5) with human thioredoxin reductase-thioredoxin

<b>Compound</b>	<b>Molecular mass</b>	<b>HBD</b>	<b>HBA</b>	<b>cLogP</b>	<b>Rotatable bonds</b>	<b>Ro5 violation</b>	<b>Docking Score</b>	<b>Distance from Sec 498(Å)</b>
<b>1</b>	735.6	2	4	7.05	8	2	-25.75	6.638
<b>2</b>	763.7	1	4	6.87	9	2	-30.20	6.514
<b>3</b>	777.7	1	4	8.41	10	2	-33.87	6.413
<b>4</b>	763.7	1	4	7.67	8	2	-34.45	2.135
<b>5</b>	791.7	1	4	8.84	10	2	316	7.675

The CLC drug discovery workbench [63] program was used to dock the gold complexes to the TrxR (PDB ID: 3EAN). However, the initial ligands were extracted from the target protein before being docked with the gold complexes. The active site in TrxR has been known to include Sec 498 (selenocysteine) which would lead to the formation of the gold-selenolate specie [121]. Hence this was used as the binding site. The complexes were all minimized using Spartan 16 program [122] before being docked in the binding site. The Discovery studio program [97] was used to observe the binding mode and interactions present in the binding pocket of the docked results. All other amino acid interactions present in the binding mode were discarded except for Sec 498. The bond distance between the gold atom present in each complex and the Selenium atom in the Selenocysteine amino acid (Sec 498) was observed using the GaussView program [92]. Complex 4 had the shortest distance of 2.13 Å (Fig. 4) between the gold and selenium which implied that it had the best potential to form the gold-selenolate specie. This bond distance is in fact shorter than what was observed between Auranofin and selenocysteine [123] which is 5.897 Å. All the complexes showed negative docking scores except complex 5 which implied that there was no binding affinity between the complex and the target protein (TrxR) since the more negative a docking score, the stronger the binding affinity. Moreover, the docking scores correlated with the bond distances between the gold and selenium atoms such that complex 4 which had the shortest bond distance also had the highest docking score and same applied to complex 5 (Table 13).

All the complexes violated the Lipinski's rule of five, by having a molecular mass and calculated logP (clogP) greater than 500 and 5 respectively. However, this does not deter

them from being used as potential anticancer therapeutics since they can all be optimized into lead compounds[124], [125].

**Figure 20.** The interaction of complex 4 with Sec 498 in the binding site of TrxR (PDB ID: 3EAN).

### 4.3.3 Molecular Docking of Ketoconazole

The docking analysis of ketoconazole (KCZ) with the crystal structure of an androgen receptor, PDB ID: 2AX6 [126] was done using CLC drug discovery workbench 3.0 [96]. Ketoconazole is the first non-steroidal compound to bind competitively to a sex steroid globulin. Amongst other antifungal imidazole derivatives such as clotrimazole and fluconazole, ketoconazole is the only one which interacts with the androgen receptor [55]. It acts as an antagonist thereby making it useful in the treatment of androgen-dependent prostate cancer [126]. However, the mode of action of ketoconazole has not really been understood. Molecular docking is an in-silico method that is used in understanding the interactions between ligand in this case, ketoconazole and a target protein (androgen receptor). The validity of the target protein using Ramachandran plot gave an outlier of 0.9%, which falls within the recommended range of 0-5% for a good quality protein [95]. The water molecules were removed before binding the ligand to the receptor and the initial ligand in the crystal structure of the target protein was used as the reference binding site within a radius of 13 Å. The number of iterations was set to 100 to get the best binding mode. After docking the ketoconazole to the androgen receptor, the ligand was optimized to give a docking score of -57.55 which implied a strong binding between the ligand and the receptor since the higher the negative value of a docking score the stronger the binding. The interactions between the ligand and the receptor showed many favorable interactions such as pi-alkyl, pi-cation, hydrogen bond and halogen bond with the amino acids found in the binding site and only two unfavorable interactions with MET 745 and GLN 711 (Fig. 21). The binding mode and molecular interactions between ketoconazole, and the androgen receptor may help understand the former's role in treating prostate cancer.

**Figure 21.** (A) Docked conformation of ketoconazole in the active site of the androgen receptor (PDB: 2AX6). (B) The molecular interactions between ketoconazole and the androgen receptor

#### 4.3.4 Molecular Docking of Methimazole

Methimazole (MTZ) is one of the popular anti-thyroid drugs alongside propyl thiouracil. It acts by inhibiting the enzyme thyroid peroxidase [15] which is responsible for the synthesis of thyroid hormone. Molecular docking helps in understanding the mode of action of methimazole on thyroid peroxidase. The structure of thyroid peroxidase was got from the protein database with PDB ID-1VGE [127]. Ramachandran plot which is a simple and popular way of validating protein structures [128] was used to confirm if the target protein was of good quality before docking it with the ligand (MTZ) using Moleman2 [95]. The percentage Ramachandran outlier for the enzyme thyroid peroxidase is 4.27%. This falls within the accepted range from a good quality protein, which is between 0-5% [95]. The AutoDock Vina [129] tool was used for the docking analysis. The ligand was first minimized before being docked with the target protein. The grid was maximized with a binding center of -22.3540, 26.5288 and 63.0403 for X, Y and Z axes respectively via the PyRx software [130]. The grid covered the whole target protein to ensure that all possible binding sites were considered to get the best binding mode. MTZ had a score value of  $-4.5 \text{ kcalmol}^{-1}$  which showed good binding affinity with the target protein since negative values implies presence of binding affinity while positive values means no binding exist between the ligand and the protein. The Discovery studio visualizer [97] was used to view the possible interactions between MTZ and the target protein, thyroid peroxidase as shown in Fig. 21. The CLC Drug Discovery workbench [96] was used to view the protein-ligand complex between MZM and the target protein. There were three types of favorable bonds present in the protein-ligand interaction of MTZ with thyroid peroxidase. The favorable bonds include the conventional hydrogen bonding to ASP167 and GLU165; a pi-sulfur with HIS 173 and a pi-donor hydrogen bond with THR164.

**Figure 22.** (A) Docked conformation of MZM in thyroid peroxidase (PDB ID: 1VGE). (B) The molecular interactions MZM and amino acids in thyroid peroxidase

### 4.3.5 Conclusion

The molecular docking analysis of MNPE showed that binding site C had the best binding affinity towards the human GABA<sub>A</sub> receptor. For the novel anti cancer seleno-complexes The molecular docking studies indicated that complex 4 had the highest binding affinity (−34.45) and showed the molecular interactions such as, van der Waals, pi-cation and alkyl with the amino group present in the target protein. Complex 4 also had the shortest bond distance between gold atom and Sec 498 of TrxR (2.13 Å), while complex 5 has the highest (7.68 Å). The molecular docking results of the complexes with human thioredoxin reductase enzyme would be helpful to explore their mechanism of action. The molecular interactions between Ketoconazole and the androgen receptor showed many favorable interactions such as pi-alkyl, pi-cation, hydrogen bond and halogen bond with the amino acids found in the binding site and only two unfavorable interactions with MET 745 and GLN 711 while the molecular docking studies of Methimazole with thyroid peroxidase revealed three types of favorable bonds including, the conventional hydrogen bond to ASP167 and GLU165; a pi-sulfur with HIS 173 and a pi-donor hydrogen bond with THR164.

## Vitae

Name : Abdulmujeeb Toluwase Onawole

Nationality : Nigerian

Date of Birth : 5/14/1989

Email : atonawole@gmail.com

Address : 10, Aruba, Sabo, Sagamu, Ogun state, Nigeria

Academic Background : B. Tech (Pure and Applied Chemistry), Ladoke Akintola University of Technology, Ogbomoso, Nigeria (2011); MSc. (Chemistry), King Fahd University of Petroleum and Minerals, Dhahran, Saudi Arabia (2017)

### Publications:
